Abstract—We implement CHUD in C#.Net. Overall four to five main modules, Connection Module, CHUD Module, DAHU Module, Dataset Population Module and Result Analysis module. The Connection Module allows us to connect our software to our database file CHUD.accdb as well as to the dataset on which utility mining should be performed. This module will collect the information about columns like ItemSold (which actually contains itemnames/itemids sold in transaction), transaction Id, item quantity, profit unit etc. As we know CHUD works on promising items only, we need to extract promising items from the given dataset. At the same time while we scan whole dataset we build an association matrix/table which is a vertical representation of given dataset. CHUD module discovers closed high utility itemsets, and records these itemsets in PhaseIOutput table in CHUD.mdb. DAHU later on uses each itemset from PhaseIOutput table and work from the top. Work from the top suggest that it operates on the itemsets of maximum length 'k' and discovers all possible high utility itemsets of length 'k-1', which not present in PhaseIOutput table. All high utility itemsets discovered by DAHU recorded in PhaseIIOutput. The both the tables Phase-I Output and Phase-II Output combine form a final result set which have all the high utility itemsets for the given dataset. C={X1, X2...Xn} where $Xi \in Phase I Output. D= \{Y1, Y2...Ym\}$ where Yi ∈ Phase-II Output. Suppose R is the final result set, then, $R = (C \cup D)$. Finally we represent the result with result pattern module, which use the data of both the table Phase-I Output and Phase-II Output, and

represent the items and itemsets with their utility value in Bar chart, PI Chart or any other representation style element. One can make a good analysis with these results.

Keywords— Closed high utility itemsets, utility Mining, Concise and lossless representation, data mining.

INTRODUCTION

Data mining is not only the process of extraction of knowledge but also representation of results towards the user.[2-11] Implementation of an algorithm which mines high utility itemsets from the given dataset must be focused on minimum memory usage as well as the time required to execute the main task. The CHUD algorithm works in bottom up manner. Where each individual item gets assessed on the basis of its utility, and then sorts them in a specific order (ascending order of support). The sorted items then considered as nodes. Each of the node then consist of itemset name, PREVSET, POSTSET, tidSet, EstU. Here itemset word is used for set if items which contains single or multiple items. An itemset name is string array which contains the set of item names. PREVSET is an array which contains all itemsets appearing before the current node. POSTSET contains all itemsets appearing after current node. Hence the first node in the list will have PREVSET as null and last node in the list has POSTSET as null. The tidSet is another array which holds the transaction

Volume: 02, Issue: 01 (JAN-FAB, 2016)

ID's in which itemset is appearing. EstU is a simple variable which hold estimated utility for the current node. All these data members form one node. A node is created for each item on an ordered list.

An AssociationMatrix table is used to represent the original dataset in vertical manner. In which first column is TransID and later columns are the total the business. Attribute AssociationMatrix table can be shown as A= {TransID, Item1, Item2, Item3...Itemn}. For example; A = {TransID, 'Tea', 'Cigarrete', 'Chewnngum'}. A value set can be explained as Av= $\{T1, 2, 5, 2\}$ where 2, 5, and 2 represents the quantity of an item in transaction ID T1. A transaction utility table is used to record the transaction utilities, which have two fields TransID, and TUtility, transaction id and transaction utility Another table UtilityEstimation respectively. records itemset utility, which has two fields itemset ID/Name and EstUtility, which is Itemset name and estimated utility of an itemset. We maintain the local transaction utility in LTU table and Global Transaction utility in GTU table. GTU table holds the utilities of all the transaction, while LTU holds the utilities of the transactions in which current node itemset is appearing. A table named PromisingItems records the promising items in the first scan. These items recorded in PromisingItems table will be used to form an ordered list and then nodes will be created for them. These nodes will send for processing to CHUD algorithm one by one. CHUD algorithm's advantage is that it holds only one node in memory at a time. Once CHUD completed execution it records closed high utility itemsets in the PhaseIOutput table along with its utility and set length (which helps in PhaseII). We have used comma as delimiter in listing the items in the same set. Here Fig. 2 shows the vertical representation of dataset present in Fig.1.

TransID	Item_Sold	 :	:	
TID1	I1(3),I2(2),I3(1)	 		
TID2	I1(2),I2(1),I5(4),I4(3)	 		

OR					
TransID	Item_Sold	Quantity			
TID1	II.	3			
TID1	<i>I2</i>	2			
TID1	<i>I3</i>	1			
TID2	II	2			
TID2	<i>I2</i>	1			
TID2	<i>I5</i>	4			
TID2	<i>I</i> 4	3

Vertical representation of above dataset

TransID	Il	I2	13	I4	15
TID1	3	2	1	0	0
TID2	2	1	0	3	4

Fig.2. Transactions in table (Vertical)

This vertical representation is stored in AssociationMatrix table.

TOOLS TESTING

To Test the tool we have developed, we had created a dataset which holds 465 records which are formed on the basis of dataset given as follows

TID	Transaction	Transaction Utility (TU)
T_1	A(1), B(1), E(1), W(1)	5
T_2	A(1), $B(1)$, $E(3)$	8
T_3	A(1), $B(1)$, $F(2)$	8
T_4	E(2), G(1)	5
T_5	A(1), $B(1)$, $F(3)$	11

Fig.3. Trainee Dataset [1]

These five transactions shown in Figure 3 are used to populate the dataset for our tool. Firstly we convert these five records in vertical manner as

Volume: 02, Issue: 01 (JAN-FAB, 2016)

shown in Fig. 4. We named A as aitem, B as bitem, E as eitem, F as fitem, W as witem and G as gitem.

Sales				
TransId	ItemSold	Qty		
1	aitem	1		
1	bitem	1		
1	eitem	1		
1	witem	1		
2	aitem	1		
2	bitem	1		
2	eitem	3		
3	aitem	1		
3	bitem	1		
3	fitem	2		
4	eitem	2		
4	gitem	1		
5	aitem	1		
5	bitem	1		
5	fitem	3		

Fig.4. Vertical Dataset

We insert the same five records in the sales table with different TransactionIDs. The dataset of five transactions get converted to vertical view, it actually spans 15 records. The first module of our tool is populating dataset bases on above 15 records. We enter same 31 data segments with different transaction IDs. Hence the minimum threshold will be now 310 instead 10. The database records are shown in figure 5. The first step is to get connected to dataset and get the columns name information required for application of CHUD. Fig. 5 shows the step-1 "Transaction utility computation". We browse the dataset file and set the connection. Clear my file clears the connection of file. Once connection set all the names of tables in database are listed in Table Name Combo Box. The columns of the table are listed in Column Names as we select

the table name automatically. Select and add columns TransactionID, ItemSold, and Quantity in left side and same in the right table add ItemName, ProfitUnit columns in right listbox respectively. The button Transaction Utility Computation then pressed for computing the transaction utility of each transaction. *Set Column Names* link button is used to remember the column names of source dataset file.

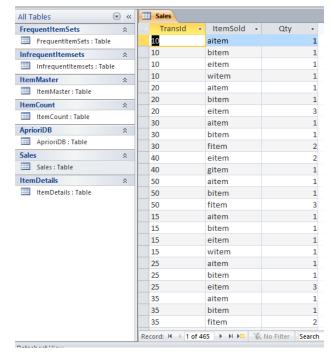

Fig.5. The dataset populated contains 465 records

Then tab Phase-I should be clicked to move on. This phase takes the input minimum utility and set of items and classifies the items as promising and unpromising labels. The promising and unpromising items are listed in the list boxes separately as shown in Fig.6. Then Phase-I operates further only on promising items. Apply CHUD button to apply CHUD algorithm on promising items. The node information will be displayed. The phase-I output is hold in Phase-I output list box. After this the output of Phase-I is carried forward to Phase-II in which the closed high utility itemsets are broken into

Volume: 02, Issue: 01 (JAN-FAB, 2016)

subsets and checked for the high utility condition. In this stage all itemsets are discovered and if any of it satisfies the minimum threshold and not present in the list of Phase-I output, will be added to Phase-II output. The list box named Phase-II output will contain the itemsets of Phase-I and Phase-II both. Then DAHU can be applied with the help of Apply DAHU button. DAHU algorithm takes itemsets from Phase-I and checks for their subsets are high utility itemsets or not.

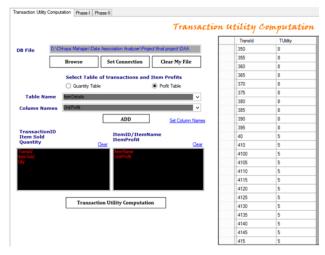

Fig.5. Connection Setting and Transaction utility computation

Fig.6. Phase-I

Finally we get all high utility itemsests listed in Phase-II combo-box as shown in Fig.7.

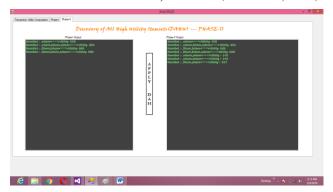

Fig.7. Phase-II (Discovery of All High utility itemset)

CONCLUSION

CHUD algorithm discovers all closed high utility itemsets efficiently. Here 'efficiently' word is used in concerned with compact and lossless representations. Such efficiency of CHUD comes from the very good strategies works with it. This implementation tested only for limited number records and items, but we can conclude that applying CHUD practically is beneficial. Because it holds only current node in memory, though the node acquires large memory than a simple node.
